A Study of Variations in the Origin of Obturator Artery in the Human Cadavers (South Indian Population)

Authors
A.Senthamizhchelvan, V.Muniyappan, P.K.Venkadachalam, R.Shanthakumar

Introduction
Variations in the branching pattern and its practical importance necessary for the surgeon to thoroughly orient himself.

Obturator artery is usually a branch of Anterior division of internal iliac artery. Its frequent variations in its origin and course has drawn attention of Anatomists, pelvic surgeons and Interventional Radiologists. The present study was conducted on Fifty (Formalin fixed) hemi sections of human cadaveric pelvic specimens, which were collected from the cadavers allotted to undergraduate students at department of anatomy, Raja Muthiah medical college, Chidambaram Tamilnadu, during 2015-2017. The pelvis was carefully dissected to study the origin, relations, within the pelvis. The findings were observed and recorded. Origin of obturator artery was from the Anterior trunk in 64% of specimen and was variable in 36% of specimen. The variations in obturator artery may lead to surgical complications during pelvic surgeries.

Keywords: obturator artery, origins, variations.

ABSRACT
Obturator artery is usually a Branch of Anterior division of internal iliac artery. Its frequent variations in its origin and course has drawn attention of Anatomists, pelvic surgeons and Interventional Radiologists. The present study was conducted on Fifty (Formalin fixed) hemi sections of human cadaveric pelvic specimens, which were collected from the cadavers allotted to undergraduate students at department of anatomy, Raja Muthiah medical college, Chidambaram Tamilnadu, during 2015-2017. The pelvis was carefully dissected to study the origin, relations, within the pelvis. The findings were observed and recorded. Origin of obturator artery was from the Anterior trunk of Internal iliac in 64% of specimen and was variable in 36% of specimen. The variations in obturator artery may lead to surgical complications during pelvic surgeries.

Materials and Methods

The present study was carried out on 50 (formalin fixed) hemisections of human cadaveric pelvic specimens, which were collected from the cadavers allotted to under graduate students at department of anatomy, Raja Muthaiya medical college, Chidambaram, Tamilnadu during 2015-2017. They were labeled from 1 to 50 left and Rtside origin of obturator artery was studied and variations in its origin were observed.

Observations

In this present study commonest source of origin of obturator artery was normal pattern ie separate branch from the Anterior division of internal iliac artery. It was seen 33hemipelvis (66%) specimens out of the 50 specimens studied. Next commoner source of origin of obturator artery was as a branch from superior gluteal artery it was seen in 6hemipelvis (12%) of specimens. other types of variation in the origin of obturator artery are depicted in the table.

Discussion

Because of variation seen in the iliac arteries many studies are conducted on this by various authors Braithwhite (1940) Jastchinski. (1891) Adachi .(1928) Reid J (1836) is credited with the first report on the variations in the origins of the obturator artery. He observed that obturator artery runs a greater risk of being injured during the operation for strangulated femoral hernia . parsons FG and keith A(1897) studied the variations in the origin of obturator artery. In a series of 55 observation, it was observed that obturator artery arouse asa separate trunk from the Anterior division of internal iliac artery in 20 cases (36.4%) from inferior epigastricartery in 10 (18.1%) separately from the hypogastric trunk of internal iliac artery in 9(16.4%) from the posterior division of internal iliac artery in 8 (14.5%) from the internal iliac before its division in 5 (9.11%) and in common with middle rectal in 3 cases.

Dubreuil – chambardell (1925) in an extensive study of 440 cases, observed that the obturator artery was a branch of internal iliac artery in 310 cases (70.5%) and a branch of Inferior epigastric artery in 130 cases (29.5%). PickJ. Anason BJ and Ashely FL (1942) in a study of 640 halves, observed an origin of obturator artery from internal iliac in 41.4%, inferior expigastric in 25%, superior gluteal in 10% inferior gluteal in 47%, internal pudendal in 3.8% and external iliac in 1.1% of cases.

Jakubowiaz m (1996) in study of 75 Cases observed that of obturator artery arose from the internal iliac artery at different levels in 92%, from inferior epigastric artery in 2.6% and external iliac artery in 1.3% of cases.

Hong HX et al (2004) OKCUG etal (2004) pongpapongsu etal (2005) and darmanis et al (2007) all observed the importance of “Coronamortis” – anomalous vascular connection between the obturator system and external iliac or inferior epigastric systems, which may be present over the superior pubic ramus in high incidence and which may be prone to Injury and bleeding during an anterior approach to acetabulumor pelvis.

The present study confirms that fact artery shows variations in respect toit source of origin. The finding of our present study confirms, with those of previous workers on the subject and depicted in table no.2. Normal origin varies from 25% to 70%.variations can range from 30% to as high as 75%.In our study origin of obturator artery from anterior division is seen in66% of the specimens. the present study is in agreement with Pai et al(2009) and Sharma(2012) et al study.
However the frequency of variation varies in most of the worker study, the inferior epigastric artery is the most frequent source of anobuturaor artery. In sumathilatha et al study variation is observed as high was 31%, and in our study it is nil.

The next common variation of obturator artery is origin from superior gluteal artery and origin of common trunk with inferior gluteal internal pudendal artery. In our study origin from superior gluteal artery is 12% and from the common trunk is 8%. In our study origin of the obturator artery from inferior gluteal artery is reported 6%, origin from internal pudendal artery is seen in 4% of the specimens and rarely origin of obturator artery from ilolumbar artery 4% reported.

Conclusion

Approximately 25% - 60% of the population of any part of the world, show variation in origin of obturator artery. In our study obturator artery taking origin from anterior division of internal iliac artery is 66% which is closely corresponds with Sharma et al study report. Among 34% of variant obturator artery, origin for superior gluteal arterys 12%, origin from common trunk of internal pudendal and inferior gluteal is 8%, origin from inferior gluteal artery is 6% origin from internal pudendal artery is 4% and from ilolumbar artery is 4%. With proper knowledge of these variations the operating surgeon, can avoid complications during pelvic surgical procedures.
