Abstract

Background: There is a link between Low Urinary Tract Symptoms (LUTS) and deterioration of sexual function in men >50 years of age and for which transurethral resection of the prostate (TURP) is considered the gold standard treatment despite the new minimally invasive surgical options.

Objectives: To evaluate the change in sexual function status after TURP in elderly Bangladeshi males.

Methods: One hundred patients presenting with BPH and treated with transurethral resection of prostate (TURP) in the Department of Urology, BSMMU, Dhaka from January 2016 to December 2016 over a period of one year were evaluated for postoperative sexual function.

Results: The mean age of the patients was 61.21±7.21 years while the mean duration of lower urinary tract symptoms was 24.3±6.40 months. Of the 91 patients with a living wife/partner, 44 (48.4%) had active sex lives preoperatively, 38 (41.8T) of them had good erections whereas 6 (6.6%) had weak erections though they were able to have satisfactory penetration. All 44 (48.4%) had normal ejaculation prior to TURP. In the postoperative follow up, 10 (22.7%) of these 44 patients reported an improvement in their sex life in terms of increased libido and improved erections. Twenty-one (47.7%) had no change in their status after TURP, but were satisfied with their sex life. The remaining 13 (29.5%) had deterioration in their status in terms of decreased libido and poor erections.

Conclusions: About 48.4% of patients with a living spouse/partner are sexually active at the time of undergoing TURP. TURF leads to a deterioration of sexual function in up to 29.5% of these patients. This includes both loss of libido and erections.

Keywords: TURP, Erection, Libido.

Introduction
Lower urinary tract symptoms (LUTS) and sexual dysfunction are highly prevalent in aging men¹; recent evidences from both community and clinical trials, in fact, have suggested a link between these two conditions.²³ Transurethral resection of the prostate (TURP), the standard surgical therapy for the treatment of bladder outlet obstruction (BOO) caused by benign prostatic hyperplasia (BPH), is also reported to cause sexual dysfunction as well. It is known that TURP may cause retrograde ejaculation, but its effect on erectile function is still controversial.⁴⁵ Previous studies have shown that the incidence of erectile
dysfunction (ED) after TURP is between 4% and 40%.\textsuperscript{4,6} According to a systematic review, approximately 75% of sexually active and potent patients experienced retrograde ejaculation and over 13% reported ED after TURP,\textsuperscript{7} although in some studies erectile function either improved after TURP or did not change.\textsuperscript{8,9} There is no data available on sexual function of the aging Bangladeshi male. There is also no Bangladeshi data on the effects of BPH on sexual function and its improvement or deterioration after TURP. This study aims to answer these questions.

**Methods**

One hundred patients aged more than 50 years planned for TURP for standard indications were evaluated for sexual function status before and after surgery during the period from January 2016 to December 2016. A 10-point questionnaire was used to subjectively assess sexual function before surgery and at 3 and 6 months after treatment. Some patients were evaluated at 12 months also. Sterile 1.5% glycine solution was used as the irrigating fluid. A 22 French 3 way Foley catheter was inserted at the end of the procedure and bladder irrigation continued for 12 to 24 hours. The catheter was removed the following morning or in some cases on the second postoperative morning. All patients voided satisfactorily after the catheter removal. There was no incidence of TUR syndrome. Follow-up visits were advised at 6 months.

**Results**

Out of the 100 patients, 9 (9.0%) had no sex partners or wives. Of the remaining 91, 44 (48.4%) were sexually active before TURP. This included 9 (9.9%) patients who were catheterized later, but were sexually active before developing acute retention (Table 1). Of the 91 patients, 44 were sexually active and 36 of them had good erections. Ten (22.7%) patients reported an improvement in their sex lives in terms of increased libido and erections. Twenty-one (47.7%) patients had no change in their sexual performance status but were satisfied with their sex life. The remaining 13 patients had poor libido or erections though they had considerable improvement in their urinary symptoms (Table 2).

**Discussion**

Libido and erection decline in men with age.\textsuperscript{10-14} The Cologne male survey,\textsuperscript{10} found that the average prevalence of erectile dysfunction was 19.2% (6% of 38-47 year olds were sexually inactive compared to 71.35% of 60-70 year old).
The Krimpen study surveyed 1688 men found 3% incidence of erectile dysfunction in those 50-54 years old and 26% in those 70-80 years old.12 This study found 48.4% of patients who had wife/partner were sexually active before TURP. Hernandez et al.\textsuperscript{15} found 59% of patients were sexually active prior to surgery. Mishriki et al.\textsuperscript{16}, in a study of 120 sexually active men before TURP, found all of them sexually active at 6 months following TURP. In this study, it was noted a decline in sexual function in 29.5% of the patients after surgery. Thus number is comparable to the 26.0% noted by Arai.\textsuperscript{17} But Hernandez et al.\textsuperscript{15} found only 5.65% incidence of deterioration in sexual function. The overall incidence of deterioration in sexual performance after prostatectomy in other studies ranges from 7% to 40%.\textsuperscript{18-21} The deterioration in function maybe a result of damage to neurovascular bundles, altered body image or complications such as incontinence or stricture.

Another issue relates to the recovery of sexual function after TURP, Hernandez\textsuperscript{15} reported an improvement in 66% of their patients, none of our patients who were inactive pre-operatively showed any improvement. However, 22.7% of those previously active had an improvement.

Conclusions
Up to 48.4% of males undergoing TURP were sexually active. One third of them experienced a decline in sexual function after surgery. Any recovery of sexual function after surgery in inactive patients was absent.
