Abstract
The circadian periodicity of plasma lipid peroxide levels and activities of superoxide dismutase (SOD), catalase (CAT) and Total antioxidant status (TAS) were studied in 50 clinically, alcoholic hepatitis proven fresh cases (age: 18-70 years) and 50 age matched healthy volunteers with diurnal activity from 06:00 to about 22:00 and nocturnal rest. A marked circadian variation in plasma lipid peroxide level was recorded in healthy subjects and alcoholic patients with significant amplitude and acrophase around 16:21 and 17:12 respectively. The acrophase tended to be delayed in alcoholic patients. Furthermore, a statistically significant circadian rhythm was found in SOD, CAT, TAS, and MDA activities in normal volunteers and alcoholic hepatitis patients (AH). SOD and CAT enzyme activity was noted to be maximum at 06:00 and minimum at 00:00 in alcoholic hepatitis patients. The circadian acrophase for GPx activity was recorded at 16:15 in normals and around 22:45 in patients. Moreover, the activity was found to be decreased at all sampling hours during 24-hours sleep-awake period in patients in comparison to healthy counterparts. The MESOR and circadian amplitude also decreased markedly. The decreased activity of measured antioxidant enzymes in pulmonary tuberculosis patients could probably be associated with oxidative stress and/or decreased anti-oxidant defensive mechanism in such patients.

Keywords: Superoxide Dismutase (SOD), Catalase, Total Anti Oxidant Status (TAS), Alcoholic Hepatitis (AH).

Introduction
Alcoholic Hepatitis is an alcohol induced disease with genetic, psycho-social and environmental factors influencing its development and manifestations. The disease is often progressive and is considered to be a major cause of morbidity and mortality. In recent years, oxidative stress has been implicated in the path physiology of a large number of disease or disorders which are initiated and/or exacerbated by pro-oxidants such as various drugs including alcohol and food additives. Besides, ingested alcohol produces
striking metabolic imbalances in the liver. It leads to the formation of reactive oxygen species (ROS). Inadequate removal of ROS may cause cell damage by attacking membrane lipids, proteins and inactivating enzymes thus mediating several forms of tissue damage. At present, except for the abstinence of alcohol abuse, there is no effective modality of either prevention or treatment. The incidence of Alcohol Hepatitis is increasing day by day specially in the developing countries including India. The present study was planned with the objectives to investigate the oxidative damage and the efficiency of antioxidant defense system in patients of alcoholic hepatitis in the socioeconomic belt of Srinagar, Garhwal, Uttarakhand.

Materials and Methods
Fifty clinically, pathologically proven fresh cases of alcoholic hepatitis (group A; age: 20-48 years) and 50 clinically healthy volunteers of either sex (group B; age: 18-45 years) were included in this study. Only minimal and moderately advanced patients of alcoholic hepatitis were included in this study. All participants were synchronized for one week with diurnal activity from about 6:00 to about 22:00 hrs. and nocturnal rest. All subjects took their usual (although not identical) meals three times daily; breakfast around 8:30 a.m., lunch around 13:30 p.m. and dinner around 20:30 p.m., without any change in their usual fluid intake. The burden of environmental temperature and pollution, if any, was common to all participants. Prior to the blood sample collection, the participants refrain from taking any drugs/preparation that would affect or alter the oxidative stress, its defensive mechanism, level and rhythm. Six millilitres of blood was collected from each subject at fixed time points for one complete 24 hour cycle, at 06:00, 12:00, 18:00 and 00:00 hrs. in plain and sterile vials containing heparin as anticoagulant. The plasma was separated and analyzed for lipid peroxides in terms of malondialdehyde (MDA) \(^{(14)}\). The haemolysate was prepared from the red cells and used for the measurement of the activities of enzymes superoxide dismutase (SOD), catalase (CAT)\(^{(15,16,17)}\). Data were evaluated by conventional statistical analyses and by the single- and population-mean cosinor procedures\(^{(18,19)}\). Accordingly, the MESOR (a rhythm-adjusted mean, usually more precise and more accurate than the arithmetic mean), the circadian amplitude (a measure of half the extent of predictable change within a 24-hour cycle; the double amplitude being a measure of total extent of change within a day predictable by the curve fitted); and the circadian acrophase (a measure of the timing of overall high values of the fitted 24-hour cosine function) were estimated. Rhythm detection was assessed by the zero amplitude (no rhythm) test at the 5% probability level.

Discussion
A marked circadian variation in plasma MDA level was recorded in healthy Indians and alcoholic hepatitis patients with significant amplitude and acrophase around 16:21 and 17:12 respectively. The circadian acrophase of plasma MDA levels occurred around 50 minutes later in patients in comparison to healthy controls; however, there was no significant difference in the MESORS of the two groups. The circadian
amplitude tends to be increased in alcoholic hepatitis patients in comparison to the healthy volunteers. However, plasma lipid peroxide levels in terms of MDA concentrations were normal in the present study, though there was a shift in circadian acrophase exhibiting the involvement of oxidative stress in such situations. Moreover, only minimal and the moderately advanced group of patients were included in this study. The present observations regarding circadian nature of plasma MDA levels in healthy volunteers were in agreement with other reports (20-22). There are no reports regarding circadian variations of circulating lipid peroxides in alcoholic hepatitis patients under tropical conditions. A statistically significant circadian rhythm was recorded in SOD and CAT concentrations in clinically healthy subjects and alcoholic hepatitis patients. SOD activity was found to be maximum at 06:00 hrs. and minimum at 00:00 hrs. in patients. Moreover, the activity was noticed to be decreased at all sampling hours during a 24-hour sleep-awake period in patients in comparison to their healthy counterparts. The MESOR and circadian amplitude also decreased markedly in alcoholic hepatitis patients suggesting decreased SOD concentrations. The circadian acrophase occurred 30 minutes later in patients as compared to healthy volunteers. Similarly, CAT activity was also noticed to be reduced at all collection hours in patients with decreased MESOR and circadian amplitude. Moreover, there was maximum swing and altered rhythm in the activity of this important antioxidant enzyme where the circadian amplitude was found to occur about 6 hours and 30 minutes later in patients in comparison to healthy subjects. The decreased concentration of measured antioxidant enzymes in alcoholic hepatitis patients could probably be associated with oxidative stress and/or decreased antioxidant defense mechanism. This probably could be the important factor for the etiopathogenesis of the disease and needs further confirmation for better supplementation of transition metals and micronutrients along with antioxidant vitamins with known antihepatic regimen. Furthermore, supplementation of today’s cocktail of hepatic drugs with antioxidant vitamins and nutrients should be advocated in the right combination and for the right length of time according to the biological clock for better therapeutic utilization and efficiency.
