Abstract
Introduction: Encephalocele is the protrusion of the cranial contents beyond the normal confines of the skull through a defect in the calvarium and is far less common than spinal dysraphism. Our objective of this descriptive case series was to determine the patterns and surgical outcomes in various types of encephalocele in our setting.

Methods: The study was carried at Department of Neurosurgery, king George Hospital, Visakhapatnam during year 2016 to 2018. Patients with encephalocele (occipital, Scincipital, parietal) admitted during year 2016 to 2018 were evaluated for their clinical features.

Results: 10 children with encephalocele were selected during the years 2016-2018. Out of these 6 were male and 4 were female. Age range was 06 days to 2 years. Most common type of encephalocele was Frontal encephalocele. All patients underwent surgery. Out of 10 only one patient was died. Postoperative follow up showed uneventful results.

Conclusion: Most common type of encephalocele is Frontal in our set up. Contents of the sac of encephaloceles are dysplastic brain tissue and there is no harm to sacrifice it.

Keywords: Encephalocele, Atrophied Brain Tissue, Surgical Excision, Folic Acid.
Material and Methods
The study was carried at Department of Neurosurgery, king George Hospital, Visakhapatnam during year 2016 to 2018. Patients with encephalocele (occipital, Scincipital, parietal) admitted during year 2016 to 2018 were evaluated for their clinical features. Complete base line investigations were performed including ultrasound, CT scan and MRI of brain. Other congenital anomalies were also noted in record. Written consent was taken. Operative and postoperative records were maintained.

Pre Operative

Intra Operative

Bifrontal Craniotomy
Exposing The Dural Defect
Closure of Defect with G Patch

Excision of Sac with Contents

Post Operative

Statistics in King George Hospital
10 children with encephalocele were selected during the years 2016-2018. Out of these 6 were male and 4 were female. Age range was 06 days to 2 years. Most common type of encephalocele was Frontal encephalocele. All patients underwent surgery. Out of 10 only two patients died. Postoperative follow up showed uneventful results. Two of our cases required postoperative VP shunt in addition to the repair of the sac. The immediate outcome was good in all except in 2 patients. Both presented with ruptured encephalocele and succumbed to meningitis. CSF leak and wound infection observed in two cases improved on conservative

Discussion
Encephaloceles represents a congenital defect of the cranium which are common congenital problem in the practice of neurosurgery worldwide. It represents a congenital defect of the cranium in which a portion of central nervous system herniates through the defect. The contents of the sac vary from small dysplastic diverticulum to a large amount of degenerative brain tissue with variable amount of CSF fluid. The bony defect can vary in size.

Male predominance was found in our series compared to other series. Elective surgery provides time for the patients to gain weight and strength and allows the surgeon to select the best technique. Most large encephaloceles required urgent surgical treatment to avoid damage to sac. In all the occipital, parietal and nasal encephaloceles there was dysplastic brain tissue which was removed safely. Postoperative hydrocephalus should be managed through ventriculoperitoneal (VP) shunts as one or two-stage procedures.

Conclusion
Early surgical management of encephalocele is not only for cosmetic reasons but also to prevent tethering, rupture, and future neurological deficits.
Complications like hydrocephalus may need to be managed with shunt surgery. Endoscopic procedures play an important role in fronto-naso-ethmoidal encephaloceles.
