Abstract
Purpose: To compare the intraocular pressure (IOP) measured by Non-Contact tonometer (NCT) and Goldmann Applanation tonometer (GAT) and their correlation with central corneal thickness (CCT) as well as the reliability of each tonometer.
Methods: 500 patients (1000 eyes) attending the ophthalmology OPD aged 18 years and above were taken up for the study. Patients with anterior and posterior segment pathologies like corneal ulcer, leukoma, staphyloma, corneal lacerations, ectatic corneal conditions, corneal dystrophies, oedema, perforations, acute angle closure glaucoma, retinal detachments, vitreous haemorrhage and unwilling patients were excluded from the study. IOP was recorded using NCT and GAT after assessing the patient’s visual acuity. Following IOP measurement, central corneal thickness (CCT) value of each patient was measured using pachymetry. All the data were collected and tabulated for statistical analysis to obtain results.
Results: In the present study there were 256 males (51.2%) and 244 females (48.8%). The mean CCT in males was 0.5350 mm and in females 0.5340 mm respectively. The mean IOP measured by NCT is 16.43 mm hg whereas the mean IOP measured by GAT is 15.43 mm hg. IOP measured by NCT is significantly higher than the IOP measured by GAT (p<0.001). When correlated with CCT all the tonometers show significant correlation with GAT showing the strongest significant correlation. NCT overestimates IOP in normal, thin and thicker corneas when compared to GAT and are statistically significant.
Conclusion: From the present study we can conclude that IOP measured by NCT is higher than GAT. NCT values are significantly higher than GAT values in thin and normal corneas whereas it overestimates more in thicker corneas. All the tonometers show significant correlation with CCT with GAT showing the strongest significant correlation in this study. So, it is always advisable to measure the corrected IOP for each and every patient after taking into account the CCT of that particular person.
Keywords: Non-contact tonometer, Goldmann applanation tonometer, central corneal thickness, Intraocular pressure.
Introduction
Glaucoma has been established as the second leading cause of blindness. The treatment of glaucoma focuses mainly on lowering intraocular pressure (IOP). The target IOP is often set to a level 20% to 30% of IOP reduction, and consequent large IOP reduction beyond 30% or even 40% in cases of advanced glaucoma.

Intraocular pressure represents a fundamental factor of ocular health and disease. Intraocular pressure is not only important in the diagnosis and management of glaucoma but also in the assessment of postoperative course of all intraocular surgical interventions.

For almost 50 years Goldmann applanation tonometer has been the gold standard for intraocular pressure measurement but its values are affected by central corneal thickness, corneal curvature and axial length, previous corneal surgeries like lasik, keratoplasty, astigmatism and corneal irregularities.

Goldmann applanation tonometer gives correct readings when corneal thickness is 500 to 525-micron metre.

Non-contact tonometer has been found to be reasonable for screening but their values should always be correlated with corneal thickness in clinical practice.

Several studies recently have found that thinner than average corneas underestimate, while thicker than average corneas overestimate the true intraocular pressure. This effect has been found to be in the effect of 1mmhg correction for every 25-micron metre deviation from a central corneal thickness of 550-micron metre.

Tonometry or the measurement of IOP, the pressure of the fluid inside the eye is usually the only modifiable factor in management of all types of glaucoma.

Aims and Objectives of the Study
1. To compare the intraocular pressure readings of Non-contact, and Goldmann applanation tonometer.
2. To correlate intraocular pressure readings with central corneal thickness.

Materials and Methods
500 random patients (1000 eyes) attending the ophthalmology outpatient department above the age of 18 years from December 2017 to July 2019 were included in this study.

After taking a proper informed consent a brief history of the purpose of their visit was taken for all patients. Following history taking the distant visual acuity was checked using the Snellen’s chart and the near vision was checked using the Jaeger’s chart. Once the vision testing was done if the patient had any refractive error an Autorefractometer was used to find out the amount of refractive error followed by an appropriate correction was given for all patients.

Next slit lamp examination was done to rule out any anterior segment pathology like corneal dystrophies, oedema, ulcer, adherent leukoma, acute uveitis, corneal opacities and corneal perforations. This was followed by measurement of the keratometric value using the Autorefractometer.

Then the patient’s IOP was recorded first using the non-contact tonometer followed by Goldmann applanation tonometer and all the values were recorded in a proforma. The central corneal thickness for each patient was measured using pachymetry and the values were correlated with IOP.

Following all these examinations dilating drops were put and the fundus evaluation was done using the indirect opthalmoscope. The posterior segment was evaluated using an ultrasound (B-Scan) if the patient had any significant cataract or any other media opacities which obscured the view of the retina.

Inclusion Criteria: People aged 18 years to 90 years with no sex predilection.

Exclusion Criteria
1. Patients with corneal opacities, corneal dystrophies, corneal perforations, infective pathologies like ulcers, leukemia,
staphyloma, acute uveitis, corneal oedema, acute congestive glaucoma, corneal ectatic conditions.

2. Patients with posterior segment pathologies like retinal detachment, vitreous haemorrhages.

3. Patients not willing to be part of study.

**Results**

**Table 1**

**Figure 1:**

In this study 1000 eyes of 500 patients were taken up. Out of 500 patients 256 were male and 244 patients were female that is 51% were male and 49% were female participants.

**Table 2:** (mean CCT in male and female)

<table>

<td>.02604</td>
<td></td>
</tr>
</tbody>
</table>

In this study the mean central corneal thickness (CCT) in males is 0.5350mm whereas in females it is 0.5340mm, which shows that in a general population female have slightly thinner CCTs when compared to males but the values are not statistically significant.

**Table 3:** (correlation between NCT IOP and GAT IOP)

<table>

<td></td>
</tr>
</tbody>
</table>

In this prospective study the mean IOP measured by the Goldmann Applanation Tonometer which is considered to be the goldstandard is 15.42 mm hg which is significantly lower than the mean IOP measured using NCT which is 16.43 mm hg. Thus, when compared with Goldmann, NCT values are higher and are statistically significant in our study.

When CCT was less than 520-micron metre the mean IOP measured using NCT and GAT were 16.12 mm hg and 16.90 mm hg. NCT values were higher than GAT and were statistically significant.

**Table 4:** (correlation between NCT and GAT IOP when CCT is <= 520 micron metre)

NCT overestimates IOP for thicker corneas whereas GAT shows higher values when CCT is less than 520-micron metre.

**Figure 2:**

![Figure 2](image)

Figure 2 is a scatter diagram showing the correlation between NCT and CCT. NCT values are correlating with CCT and is statistically significant.

**Figure 3:**

![Figure 3](image)

Figure 3 shows the correlation between the IOP measured using GAT and central corneal thickness. Although all the tonometers show statistically significant correlation with CCT but GAT has shown the strongest correlation in this present study. From this we can come to the conclusion that variations in the CCT will affect GAT values more than NCT.

**Discussion**

Gunvant et al reported that an increase of 1 mm of mean corneal thickness was accompanied by a rise in IOP of 1.14 mmHg measured by GAT, but this effect was weak and not statistically significant.\(^1\) It is now known that GAT values are affected by CCT. In our prospective study we found that all the tonometers that is NCT, and GAT are significantly affected by the CCT of that particular person with GAT showing the strongest correlation followed by NCT in a general population.

Mark suggested that a flatter cornea might lead to lower GAT measurements which is similar to what we found in our study that GAT values are affected by CCT.\(^2\)

Chakrabarty L et al concluded that, NCT and GAT measurements showed good agreements proving that both are reliable methods of measuring IOP. In this study, slight overestimation of IOP measurement was found by NCT in lower IOP ranges (<12mmHg). Contrary to some studies, good correlation between GAT and NCT in higher IOP ranges was found.\(^3\)

In our study we found NCT values were significantly higher than that of GAT and the values were statistically significant.

Shih et al. had an objective to ascertain whether CCT affected patient management. Their study, although set within a specialist glaucoma service, showed that half their study population required an adjustment of IOP ± 1.5 mmHg. What is interesting is that 8–10% of their cohort had a change in their medication.\(^4\)

In a study by Ehlers et al, a manometric, controlled closed system was used to examine the correlation between CCT and IOP measured by applanation tonometry in 29 patients. Ehlers et al reported an error of ±0.71mm Hg between real IOP and IOP measured by applanation tonometry per 10-μm difference in CCT. Corneal curvature affected IOP readings in the study by Ehlers et al.\(^5\)

In the present study also both the NCT and GAT values were significantly affected by the CCT of that particular person. NCT shows higher values for thicker corneas whereas GAT shows higher IOP when CCT is less than 520-micron metre.
Ismail et al. reported that in eyes that had undergone penetrating keratoplasty, GAT measurements may be less precise than non-applanation tonometry because all these patients will not have normal CCT post-surgery. These findings are also similar to what we found in our study that GAT values are affected by CCT and although it is the gold standard true IOP should be recorded in all patients so that the CCT of that particular person is also taken into account.6

Kirwan et al. found that the mean GAT IOP decreased 3.7+/-2.3 mm Hg following LASIK, and a similar decrease was observed following LASEK.7

Milla et al. found an optimal agreement between DCT and GAT when the CCT was between 540 and 545 μm. As the CCT and the IOP increase, the difference between both tonometers also increases.8

Francis et al. reported that K (corneal curvature) affects DCT readings.9

Medeiros et al. reported that K affects GAT readings.10,11

S. Nagarajan et al. concluded that both Schiotz and NCT showed significant correlation with the gold standard technique over a range of IOP and CCT with the Schiotz tonometer performing better than NCT.12

In two studies in which the Reichert NCT was used (Jorge et al.2002; Jorge et al.2003) was used both in normal subjects and patients with glaucoma, excellent agreement with GAT measurements was observed which is contrary to what we found in our study where there was significant difference between NCT and GAT readings with NCT readings being significantly higher than GAT readings in a general population.13

However, Domke et al. 2006 noted that measurements of Reichert NCT are conditioned by CCT. which is similar to our findings where NCT readings were influenced by CCT.14

NCT values are higher for thicker corneas whereas GAT values are higher for thinner corneas.

Parker et al. compared NCT and GAT and found results were concordant between the two devices which is different from what we found in our large prospective study.16

In another study, Tonnu et al. compared NCT, TPXL, and GAT and reported that all three devices showed homologous results.15

Farhood showed that NCT and GAT were not well correlated, and NCT measurements gave higher IOP results regardless of the patient’s age or sex. In particular, when the GAT measurement exceeded 24 mmHg, the difference in readings between the two instruments increased. Farhood reported that the lower the IOP as measured by GAT, the more reliable the corresponding NCT readings.17

This is in accordance to what we reported in our study.

The NCT and TPXL are easier and faster to use than the GAT, but suspicions about their results still exist. Yilmaz et al. found no significant differences between these three devices in normotensive patients.18

Feng et al. also found the noncontact tonometry to overestimate IOP relative to GAT for thicker CCT which is similar to what we found in our study.22

Loewen et al. reported that AXL had a significantly negative correlation with 24 h IOP fluctuation.19

Lee SY et al. said in their study central corneal thickness (CCT), corneal curvature (CC), and axial length (AXL) demonstrated significant correlation with GAT fluctuation in the high IOP fluctuation group, and AXL showed significant correlation with DCT fluctuation in the low IOP fluctuation group. We only found CCT to significantly affect IOP readings in the 2 tonometers used by us.20

Cook et al. conducted a meta-analytical study comparing 8 tonometers and concluded that GAT continues to be the gold standard. It was observed that NCT was having least disagreement with GAT which is again contrary to what we found in the present study.23
Although NCT is also widely used the correlation observed between measurements obtained using this type of tonometry and conventional applanation tonometry has never been particularly good (Vernon 1995; Tonnu et al. 2005; Lafaut et al. 2007; Ogbuehi & Almubrad 2008). 

Studies conducted by (Grieshaber MC et al, Kamppeter BA et al, Kaufmann C et al) have reported a significant positive correlation between GAT and CCT similar to our study. 

Studies conducted by Schneider E et al, Kniesedt C et al, Ku JY et al found no correlation between GAT values and central corneal thickness which is contrary to what we found in our large prospective study. 

Y. Harada et al found central corneal thickness significantly correlated with IOP measured by NCT and that measured by GAT. Corneal curvature radius significantly correlated with IOP measured by GAT, however not significantly correlated with that measured with NCT. 

Punit Singh et al concluded that IOP measured by both NCT and GAT was significantly correlated with CCT. NCT readings were significantly higher in the thicker group (CCT≥530 micron) than in the thinner group (CCT<530 micron). GAT readings had no difference between the thicker and thinner groups. 

Babalola et al and Tonnu et al also showed that changes in IOP measured with NCT are more dependent on CCT than IOP measured by Goldmann tonometer. 

Behrooz Kouchaki et al found a linear relationship between IOP and CCT. 

**Conclusion**

IOP measurement is one of the most important investigation that an ophthalmologist will do in his daily practise. It has got immense importance as it is one of the risk factors of glaucoma and is also the only modifiable risk factor in glaucoma. So, an accurate measurement of the IOP is of paramount importance in the general population in order to say whether the person is at risk of developing glaucoma or has glaucoma. 

Goldmann applanation tonometer has been the gold standard for measuring IOP since it was discovered. Although it has been the gold standard it has its own advantage and disadvantages. Many other tonometers are there which work on the applanation principle as well as on other principles but has not been able to replace Goldmann as the goldstandard. 

It has been well documented in literature that Goldmann values are affected by CCT and also there are disadvantages like chances of infection and there is a learning curve to mention a few. 

On evaluating 500 patients and 1000 eyes we came to the conclusion that NCT values are higher than that of GAT and they are statistically significant. NCT values were higher for thicker corneas and GAT values were higher for thinner corneas in a general population. 

When the correlation of CCT with IOP measured by all these tonometers were assessed we found that all the tonometers were significantly affected by CCT. The correlation was statistically significant and we found that Goldmann values are more likely to be affected by CCT followed by NCT. So, from the present study we can conclude that the 2 tonometers are reliable and can be used in the daily practice of an ophthalmologist. When CCT was taken into account we found it affected GAT readings the most followed by NCT. So, it is always advisable to calculate the corrected IOP in all patients so that we can get the exact IOP of that particular person.
