Abstract
Introduction: Organophosphorus poisoning is of great concern in developing world as it affects the most productive age group of the society and has a high case fatality rate.
Objective: To assess the role of Serum acetylcholinesterase Levels in predicting morbidity and mortality in Acute Organophosphorus Poisoning.
Methodology: A prospective two year study was conducted to evaluate the possible impact of serum acetylcholinesterase levels on mortality and morbidity of patients admitted in ICU with diagnosis of Acute organophosphorus poisoning.
Results: A total of 102 cases were studied. The study revealed that the patients with serum acetylcholinesterase level <2300 IU/l at presentation have greater morbidity and the patients with serum acetylcholinesterase level <1800 IU/l at presentation have greater mortality.
Conclusion: It can be suggested that the serum acetylcholinesterase levels can be used to predict mortality and morbidity in low resource settings of developing world.
Keywords: Organophosphorus, Prognosis, Poisoning, Acetylcholinesterase.

Introduction
Organophosphorus (OP) compounds are widely used as insecticides in the agricultural parts of the world. Its poisoning, both intentional and accidental, is a major global problem with a case fatality rate of 4-30%. It is of great concern in developing world as it incidence is higher in young, economically active group of the society.¹ Toxicity of organophosphorus compounds is the result of inhibition of acetylcholinesterase. The rapid accumulation of acetylcholine in the synaptic junctions of CNS and peripheral tissues results in range of muscarinic, nicotinic and central effects.² Intermediate syndrome or type II paralysis usually occurs after 24-96 hours after acute cholinergic crisis.³ Death usually occurs due to cardiovascular and respiratory failure.⁴ The initial management of acute OP poisoning
includes cardiorespiratory stabilization, decontamination, gastric lavage and activated charcoal.\(^5\) The mainstay of treatment is atropine and pralidoxime.\(^6\)

A number of systems have been proposed for predicing outcome in organophosphorus poisoning, some rely on laboratory tests and others that use clinical parameters. The present study was conducted to assess the role of serum acetylcholinesterase in evaluate possible predicting mortality and morbidity of acute organophosphorus poisoning which will help in appropriate allocation of resources, including intensive care unit in a resource constrained setting.

**Aim and Objective**

To assess the role of Serum acetylcholinesterase Levels in predicting morbidity and mortality in Acute Organophosphorus Poisoning.

**Methodology**

A hospital based prospective study was conducted over a period of two years in Intensive care unit of a tertiary care teaching hospital. Following approval by institutional ethical committee and informed patient/attendant consent, all the patients of organophosphorus (OP) poisoning, diagnosed on the basis of clinical history and examination were included in the study. After initial assessment and resuscitation, all the patients were followed till the time of discharge/death and evaluated. Serum acetylcholinesterase levels were measured on admission.

The possible impact of Serum acetylcholinesterase levels on mortality and morbidity factors(duration of hospital stay, need of admission to intensive care unit(ICU), and mechanical ventilation )were assessed.

**Statistical Analysis:** The data was analyzed using SPSS software version 20. The variables of interest were tabulated in terms of frequency and percentage. Pearson's chi square test was used to calculate \(p\) value. A two- tailed \(p\)- value less than 0.05 was considered to be statistically significant.

**Results**

**Mortality and Serum Acetylcholinesterase levels**

A total of 15 cases expired out of 102 cases studied yielding a mortality rate of 14.7%.

<table>
<thead>
<tr>
<th>Serum Acetylcholinesterase levels((\text{IU/L}))</th>
<th>Survived</th>
<th>Expired</th>
<th>(p) value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3367.4</td>
<td>1763.60</td>
<td>(&lt;0.0001)</td>
<td></td>
</tr>
</tbody>
</table>

A statistically significant difference was noted between the patients who survived and those who expired.

**Morbidity parameters and Serum acetylcholinesterase levels**

**Hospital Stay**

Hospital stay was less than 7 days in 71 cases(69.6%) and more than 7 days in rest of the cases.

**Table 1:** Comparison of the Serum acetylcholinesterase levels between Patients who Survived and Expired

<table>
<thead>
<tr>
<th>Serum Acetylcholinesterase levels((\text{IU/L}))</th>
<th>Hospital Stay &lt;7 days</th>
<th>Hospital Stay &gt;7 days</th>
<th>(p) value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3510.4</td>
<td>2264.2</td>
<td>(&lt;0.0001)</td>
<td></td>
</tr>
</tbody>
</table>

A statistically significant difference was noted between the patients who had hospital stay < 7 days and hospital stay > 7 days.

1. **Admission to intensive care unit (ICU)**

A total of 64 (62.7%) patients needed admission to intensive care unit ,out of which 62 required mechanical ventilation.

**Table 2:** Comparison of the Serum Acetylcholinesterase levels at presentation between Patients who had hospital stay < 7 days and hospital stay > 7 days

<table>
<thead>
<tr>
<th>Serum Acetylcholinesterase levels((\text{IU/L}))</th>
<th>Not admitted to ICU</th>
<th>Admitted to ICU</th>
<th>(p) value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4792.45</td>
<td>2125.63</td>
<td>(&lt;0.0001)</td>
<td></td>
</tr>
</tbody>
</table>

A statistically significant difference was noted between the patients who had hospital stay < 7 days and hospital stay > 7 days.
A statistically significant difference was noted between the patients who were admitted to ICU and who did not required admission to ICU.

2. Need of mechanical ventilation

A total of 64 (62.7%) patients needed admission to intensive care unit, out of which 62 required mechanical ventilation.

Table 4: Comparison of the Serum Acetylcholinesterase levels at presentation between Patients with or without requirement of mechanical ventilation.

<table>
<thead>
<tr>
<th></th>
<th>Not ventilated</th>
<th>Required ventilation</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum Acetylcholinesterase levels (IU/L)</td>
<td>4762.45</td>
<td>2125.63</td>
<td>≤0.0001</td>
</tr>
</tbody>
</table>

A statistically significant difference was noted between the patients who were required mechanical ventilation and who did not required mechanical ventilation.

3. Duration of mechanical ventilation

Out of total 62 cases, 8 cases were ventilated for more than 3 days.

Table 5: Comparison of the Serum Acetylcholinesterase levels between Patients with duration of mechanical ventilation <3 days and >3 days.

<table>
<thead>
<tr>
<th></th>
<th>Duration &lt;3 days</th>
<th>Duration &gt;3 days</th>
<th>P value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum Acetylcholinesterase levels (IU/L)</td>
<td>3512.44</td>
<td>2268.26</td>
<td>≤0.0001</td>
</tr>
</tbody>
</table>

A statistically significant difference was noted between the patients with duration of mechanical ventilation <3 days and >3 days.

Discussion

Organophosphorus poisoning is one of the most common poisoning in developing world due to their easy availability and ignorance about their proper handling and toxicity. Despite high mortality and complications associated with it, no definite prognostic criteria have been set, which might help to assess patients at presentation. Studies have advocated use of various scales and parameters to assess the severity of poisoning and prognosis. Peradenya organophosphorus poisoning (POP) scale, modified Driesbach criteria, Glasgow coma scale, APACHE II, SAPS, SOFA, serum cholinesterase levels, serum amylase, serum lipase, creatinine kinase and prolonged QT interval are a few among them. Our study assessed the role of serum acetylcholinesterase levels at presentation on mortality and morbidity. Serum acetylcholinesterase levels at presentation were significantly higher in the patients who survived than patients who expired. Similar results were obtained by Rehiman et al.

Patients with shorter hospital stay, who were not admitted in ICU and did not require mechanical ventilation had higher levels of Serum acetylcholinesterase on presentation. This finding was consistent with studies conducted by Kang et al, Many et al and Banday et al. Need of ventilation is also more in patients with low serum acetylcholinesterase levels.

The serum acetylcholinesterase can be used for confirmation of diagnosis and for predicting patients who are at increased risk of mortality and morbidity. It is suggested that the patients with levels of serum acetylcholinesterase less than 2300 IU/L should be immediately referred to an Intensive care Unit with possibility of need for mechanical ventilation. In resource constrained settings, it will help in decision making regarding referral to a higher center or for keeping patients under observation, after initiation of treatment and can lead to significant reduction of mortality and morbidity resulting from acute organophosphorus poisoning.

Conclusion

It is concluded that Serum acetylcholinesterase levels <2300 IU/L on presentation have greater morbidity and mortality in our setup. It is suggested that the patients with these levels of serum acetylcholinesterase should be immediately referred to an Intensive care Unit with possibility of need for mechanical ventilation. In resource constrained settings, it will help in decision making regarding referral to a higher center or for...
keeping patients under observation, after initiation of treatment.
